03 Synthesis and characterisation of YBCO (Superconductor)

Aim: Prepare the superconductor YBa$_2$Cu$_3$O$_{7-\delta}$ with different oxygen content.

Characterization: Powder diffraction and resistivity measurements.

Technique: Solid state reaction of oxide materials

Material properties: Superconductor.

Chemicals: Y$_2$O$_3$
BaO$_2$
CuO

Instructions:
1) The powders are weighed stoichiometrically to obtain the correct ratio between Y:Ba:Cu, which is 1:2:3, the resulting oxygen content nominally exceeds 7.
2) The powders are ground and packed loosely into an Al$_2$O$_3$ crucible.
3) The crucible is placed in a furnace and heated to 940°C, and held there for 12 hours. The product is furnace cooled.
4) The powder is reground and pressed into pellets. Use ~2 cm dies for pressing. The pressed pellet is furnace heated to 940°C and slowly cooled to room temperatures. Samples are removed at temperature intervals to introduce oxygen deficiencies (e.g. in steps of 100°C from 600-500°C down to room temperature).
5) Powder diffraction investigation to establish unit cell size
6) Phase transition temperature is measured utilizing the Meissner effect.
7) Oxygen content is determined by volumetric method.

**Determination of oxygen content using iodometric titration**

Iodometric titration can be used to determine the Cu\(^{2+}\) and Cu\(^{3+}\) concentration. The Cu\(^{3+}\) concentration is proportional to the amount of oxygen in the sample.

\[ \text{Y}^{3+}\text{Ba}^{2+}\text{Cu}_{3-x}^{2+}\text{Cu}_x^{3+}\text{O}_y^{2-} \]

In principle these experiments should be performed under inert atmosphere to avoid oxidation by air, but this unfortunately we cannot do.

We need two experiments to determine \(x\). Experiment A) YBCO is boiled in HCl to transform Cu\(^{3+}\) to Cu\(^{2+}\) the titration gives the total amount of Cu in the sample. B) the sample is dissolved in HCl and titrated directly giving the concentration of Cu\(^{2+}\) and Cu\(^{3+}\), now since Cu\(^{3+}\) produces more I\(_2\) is possible to extract the Cu\(^{3+}\) concentration of the sample and thus the oxygen content.

Three experiments of each titration are done to allow calculation of mean and average value – this gives a total of 6 titrations.

A) Total concentration of Cu\(^{2+}\).

About 30 mg of YBCO is dissolved in approximately 5ml 1M HCl and boiled for 10 min. Cu\(^{3+}\) is hereby reduced to Cu\(^{2+}\).

10 ml 0.7 N KI is added.

Titration using thiosulfat see concentration in the lab – should be around 0.1 M (so you need approximately 1 mL).

Close to the equivalence point starch is added.

The processes taking place are

\[ 2\text{Cu}^{2+} + 4\Gamma \rightarrow 2\text{CuI} + I_2 \]
\[ 2\text{S}_2\text{O}_3^{2-} + I_2 \rightarrow \text{S}_4\text{O}_6^{2-} + 2\Gamma \]

B) The YBCO is dissolved in 7 ml of 0.7M HCl.

Add 7 ml of 1M KI

Start titration using thiosulfate

The processes taking place are

\[ \text{Cu}^{3+} + 3\Gamma \rightarrow \text{CuI} + I_2 \]
\[ 2\text{Cu}^{2+} + 4\Gamma \rightarrow 2\text{CuI} + I_2 \]
\[ 2\text{S}_2\text{O}_3^{2-} + I_2 \rightarrow \text{S}_4\text{O}_6^{2-} + 2\Gamma \]

The titration of Cu\(^{3+}\) corresponds to the double concentration compared to Cu\(^{2+}\) Subtracting the used volumes of S\(_2\)O\(_3\)^{2-} in A and B gives the concentration of Cu\(^{3+}\). Using the oxidation state of the individual elements in YBCO and neutrality – the total oxygen concentration can be found.
